#### Abstract

Syntheses of inwardly and outwardly directed allylsilanes those are tethered to new inherently chiral cavitands are described. Oxidized with mCPBA, these allylsilanes result in diastereomeric mixtures of epoxide molecules. Thus, it enables us to have comparative study of cavitand-structure diastereo-

selectivity relationship, which revealed that an inward allylsilane group flanked by a dibenzo[f, $h]$ quinoxaline and two bridged methylene groups have the best chemical yield and diastereoselection.

## Introduction

Synthetic organic compounds that contain an enforced cavity are defined as cavitands. ${ }^{[1]}$ Cavitands impose a curved boundary that encloses an empty space. ${ }^{[2]}$ The presence of such curvature can, in special circumstances, result in an asymmetric framework, that is "inherent chirality." Inherent chirality differs from point chirality, axial chirality, planar chirality, and helical chirality. ${ }^{[3]}$ Cavitands that exist as enantiomers but lack other asymmetry elements (e.g. point chirality) have inherent chirality. ${ }^{[4,5]}$ Inherently chiral cavitands have been synthetically difficult to prepare, even as racemates. Additionally, maximizing use of the curved space requires careful inwardly positioning of reactive centers. ${ }^{[6]}$ Consequently, investigations on nature and potential of inherently chiral cavitands remains unexplored, even though they promise have strong potential for the progress of chiral science. ${ }^{[7]}$

Herein we report the syntheses and properties of new allylsilanes derived from the racemic diol rac-1 (Figure 1). The rac-1 possesses inherent chirality, which is stable because inversion of the resorcin[4]arene skeleton is impossible. Importantly, inwardly directed allylsilane rac-2 and outwardly directed allylsilane rac-3 were isolated. The epoxidation reaction of rac-2 and rac-3 would give rise to diastereomeric isomers (Scheme 1). The

[^0]questions we pursue here are "How effective can inherently chiral cavitands relay their chirality to prochiral substrates?" "Can this new asymmetric framework induce chiral diastereo-enriched compounds?" In the pursuit of these questions, we also prepared rac-4 to rac-11 that possess different electronic and steric feature in an effort to more thoroughly understand the principles at work in inherently chiral spaces by studying the diastereoselection of allyl oxidation (Figure 2).

Figure 2. Four new pairs of isomers are rac-4/rac-5, rac-6/rac-7, rac-8/rac-9, and rac-10/rac-11. Introverted allylsilanes are rac-4, $-\mathbf{6},-\mathbf{8}$, and $-\mathbf{1 0}$, and extroverted allylsilanes correspond to rac-5, -7, $\mathbf{- 9}$, and $\mathbf{- 1 1}$.

## Results and Discussion

Routes for syntheses of rac-1 and the corresponding allylsilanes rac-2-rac-7 are illustrated in Scheme 2. Preparation of cis-positioned diquinoxaline-spanned resorcin[4]arene was laborious, ${ }^{[8]}$ but the use of DABCO (1,4-diazabicyclo[2.2.2]octane) and pyridine pushed the chemical yield to $22 \%$. The cis-positioned tetraol is a prochiral platform for producing asymmetric molecules: the platform reacted with $\mathrm{CH}_{2} \mathrm{BrCl}, 2,3$-dibromopyrazine, and 2,3-dichloro-7,8-dimethylquinoxaline ${ }^{[9]}$ to yield rac-1 in $44 \%$, rac-12 in $27 \%$, and rac-13 in $55 \%$, respectively. ${ }^{[10,11]}$ The resolution of rac-1 was performed by analytical HPLC using a Chiralpak IG column singly eluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in flow rate $1 \mathrm{~mL} / \mathrm{min}$ at $25^{\circ} \mathrm{C}$, which afforded two peaks of $t_{\mathrm{R}}=4.0 \mathrm{~min}$ and 7.4 min with perfect separation, confirming the presence of two enantiomers. ${ }^{[12]}$ Then, the rac-1, rac-12, and rac-13 reacted with commercially available allyl(dichloro)methylsilane, giving isomeric products of inward and outward allyl compounds those
are rac-2/rac-3, rac-4/rac-5, and rac-6/rac-7, respectively. ${ }^{[13]}$ The separation of these isomers ( $\mathbf{2}$ from $\mathbf{3}, 4$ from 5, and 6 from 7), which were prepared in roughly 1:1 ratios was an embarrassing operation.

Scheme 3 shows synthetic routes to allylsilanes rac-8-rac11 that are based on trans-positioned diquinoxaline-spanned resorcin[4]arene. The trans-positioned tetra-ol reacted with 2,3-dichloro-6-methylquinoxaline and 2,3-dichloro-6-fluoroquinoxaline in $46 \%$ of rac-14 and $39 \%$ of rac- $\mathbf{1 5}$ yields, respectively. ${ }^{[14]}$ The racemates of rac-14 and rac-15 comprises two enantiomers bearing inherent chirality like rac-1, which lead to the corresponding allylsilanes of rac-8, -9, -10, and $\mathbf{- 1 1}$.

We made the following observations about the solution dynamics of these allylsilanes derivatives. ${ }^{[15]}$ Typically, chemical shifts of the methine protons below the quinoxaline moieties, like $\mathrm{H}^{\mathrm{a}}$ and $\mathrm{H}^{\mathrm{b}}$ (Table 1), explain the behaviour: the protons around 5.5 ppm are indicative vase conformers, whereas

3.7 ppm indicates the kite form. ${ }^{[16]}$ Protons $\mathrm{H}^{\mathrm{c}}$ and $\mathrm{H}^{d}$ reside in an electronic different from the other protons $\mathrm{H}^{\mathrm{a}}$ and $\mathrm{H}^{\mathrm{b}}$. The summarized chemical shifts of the methines $\mathrm{H}^{\mathrm{a}}-\mathrm{H}^{\mathrm{d}}$ are found in Table 1. $\mathrm{H}^{\mathrm{a}}$ and $\mathrm{H}^{\mathrm{b}}$ in both $\mathrm{CDCl}_{3}$ and $\left[\mathrm{D}_{8}\right]$ toluene are found between 5.6 and 6.2 ppm , respectively. This observation is in agreement with the vase-kite switching cavitands, in which a class of quinoxaline walled cavitands prefer vase conformers.

The chemical shift difference between in- and out-isomeric allylsilanes is also documented (Table 2). Protons $\mathrm{H}^{\mathrm{e}}-\mathrm{H}^{i}$ belong to methyl and allyl groups on silicon, and because of the magnetic shielding caused by the cavity, inwardly directed protons shift upfield. ${ }^{[17-19]}$ These chemical shifts are summarized in Table 2. The $\mathrm{CH}_{3}$ protons $\mathrm{H}^{\mathrm{e}}$ of rac-2, -4, $-\mathbf{6},-\mathbf{8}, \mathbf{- 1 0}$ nearly positioned at 0.45 ppm , although those of rac-3, -5, -7, -9, $\mathbf{- 1 1}$ shifted upfield to around -0.50 ppm . On the other hand, the $\mathrm{CH}_{2}$ protons $\mathrm{H}^{f}$ of rac-2, $-4,-6,-8,-\mathbf{1 0}$ shifted to more upfield ca. 1.0 ppm than those of rac-3, -5, -7, -9, -11 nearly at 2.0 ppm . These mean that $\mathrm{H}^{\mathrm{f}}$ of rac-2, -4, -6, -8, -10 and $\mathrm{H}^{\mathrm{e}}$ of rac-3, $\mathbf{- 5},-\mathbf{7},-\mathbf{9},-\mathbf{1 1}$ are enclosed by the interior space: thus, the orientation of the substituents on the silicon atoms was determined. In addition, we summarized the difference in chemical shifts ( $\Delta \delta$ values) between each two-isomeric allylsilanes (Table 3). The protons of the $\mathrm{H}^{e}\left(\mathrm{CH}_{3}\right)$ and $\mathrm{H}^{\dagger} / \mathrm{H}^{f}$ $\left(\mathrm{CH}_{2}\right)$ directly bonded to the silicon atoms show relatively large values of approximately $0.82-1.84$ as compared to the corre-
sponding values of $\mathrm{H}^{g}, \mathrm{H}^{h}$, and $\mathrm{H}^{i}$. This means the closest position to the silicon atom is most sufficiently covered by the anisotropic effect of the strong $\pi$-surrounding induced by the inner space. In addition, it is especially noteworthy that only geminal protons $\mathrm{H}^{\mathrm{f}} / \mathrm{H}^{\mathrm{f}}$ of rac-2 and rac-4 reflect the asymmetry and are distinguishable from each other. The corresponding $\mathrm{H}^{f}$ protons of other cavitands are free from influence of the dissymmetrical $\pi$-space, even if they are placed inside or not and partitioned or not.

With the success in structural evaluation of series of cavitands, ${ }^{[20]}$ we eventually set out to study the diastereomeric ratios that result from epoxidation of allylsilanes rac-2-rac-11. The results are summarized in Table 4. MCPBA (meta-Chloroperbenzoic acid) in toluene was used at room temperature. After 12 hours reaction showed completion by TLC. Inwardly directed allyl groups were more reactive than their outward counter-

[c] Determined in ${ }^{1} \mathrm{H}$ NMR spectra ( $400 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ) on the basis of singlet peaks those are corresponding to the aromatic protons in resorcin[4]arene skeletons (for rac-2, -4, -6, -8, -10) and protons in epoxide ring moieties (for rac-3, -5, -7, -9, -11). These peaks were totally separated between diastereomeric isomers. ${ }^{1} \mathrm{H}$ NMR stacks are summarized in Figure S 2 and Figure S 3 of Supporting Information. parts: these phenomena were observed in our previous report, ${ }^{[13]}$ in which the inside $\pi$-cloud actively stabilizes the reaction. For diastereomeric ratios, better distributions of ca. 60:40 were observed with inwardly directed allyl groups found in rac2 and rac-4. These variants have two short walls compared to the others in the series (entries 1 and 3 ). The larger walls of rac-6-rac-11 gave almost ca. 50:50 diastereomeric ratios, independent allyl group orientation (entries $5-12$ ). This indicates that having one opening (or low height wall) is advantageous for diastereoselection of the prochiral allyl group.

Using this data, we designed a final candidate rac-16 that is bridged with two methylenes and one wider dibenzo[ $f, h]$ quinoxaline (Figure 3). A straightforward synthetic route to rac-16 and its derivative allylsilanes rac-19/rac- $\mathbf{2 0}$ are illustrated in Scheme 4. The tetra-ol platform was bridged with two methylene units in $79 \%$ yield of $\mathbf{1 7}$, and this was followed by removal of two quinoxaline walls in $68 \%$ yield of $\mathbf{1 8}$. Then, reaction of 18 with 2,3-dichloro-dibenzo[f,h]quinoxaline afforded rac-16 in $41 \%$ yield, although a side-product of two-walled cavitand was accompanied in $15 \%$. Finally, rac-16 was converted into inward allyl rac-19 in $26 \%$ yield and an outward allyl rac-20 in $12 \%$ yield. Chemical shift analysis is consistent with our prior cavitands above, meaning that rac-19 and rac-20 are in the vase shape (Table 5 and Table 6).

Given the stereo-defined synthesis of allylsilanes rac-19, and $\mathbf{- 2 0}$, we then investigated structural effects on diastereo-

selective production in epoxidation reactions (Table 7). The rac19 afforded the highest diastereomeric ratio of 64:36 with excellent chemical yield of 84 \% (entry 1). In contrast, the reaction of rac-20 resulted in an even 50:50 diastereomeric ratio with low 42 \% yield (entry 2). These results confirm our earlier observation: the asymmetric compartment partitioned is effective when a mix of tall/wide groups and much smaller bridging groups provides for the inherent chirality of the system. Very likely, this will result in a strong preference for selective approach of mCPBA to the more accessible prochiral face of the allyl carbon-carbon double bond.

[a] Conditions: allylsilanes ( $0.019 \mathrm{mmol}, 30 \mathrm{mg}$ ), mCPBA ( 25 \% water contained, $0.028 \mathrm{mmol}, 6.4 \mathrm{mg}$ ), dry toluene ( 1 mL ). [b] Isolated yields of diastereomeric mixtures of resultant epoxides. [c] Determined in ${ }^{1} \mathrm{H}$ NMR spectra ( $400 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ) on the basis of singlet peaks those are corresponding to the aromatic protons in resorcin[4]arene skeletons (for rac-19), and protons in epoxide ring moiety (for rac-20). These peaks were totally separated between diastereomeric isomers. ${ }^{1} \mathrm{H}$ NMR stacks are summarized in Figure S2 and 3S of Supporting Information.

## Conclusions

In summary, we have studied syntheses of racemic cavitand compounds having inherent chirality. These compounds were further elaborated by the covalent insertion of an allylsilane that exists as a pair of in-out isomers that were separable. Oxidation of this suite of compounds allowed us to directly observe diastereomeric ratios and relate those to the features that give rise to inherent chirality of the cavitand species. Comparative study of structure-diastereoselectivity relationships strongly suggests several salient features that will direct future study. Firstly, the cis-diquinoxaline-spanned resorcin[4]arene works as a platform for diverse syntheses of inherently chiral cavitands. Second, a mixture of small bridging methylene groups and much taller, flatter walls gave higher diastereomeric ratios and good conversion of the starting allyl substrates when they were inwardly directed. This confirms both reaction stabilization and effective blocking of one pi-face of the allyl group. Third, one large dibenzo$[f, h] q u i n o x a l i n e ~ w a l l s ~ i s ~ s u f f i c i e n t ~ t o ~ h a v e ~ d i a s t e r e o s e l e c t i o n ~ a n d ~$ resulted in the best chemical yield and stereoselection. Finally, outwardly directed allyl groups did not experience any effects from the inherent chirality that the cavitands possess under these reaction conditions. These features illustrate relevance of the quinoxaline resorcin[4]arene cavitands to the design of new asymmetric reactors, reactions, and catalysis. ${ }^{[21,22]}$ Further development along these avenues is in progress.

## Experimental Section

General Methods: All reactions sensitive to air or moisture were carried out under an argon or a nitrogen atmosphere and anhydrous conditions unless otherwise noted. Dry solvents were purchased and used without further purification and dehydration. All reagents were purchased and used without further purification. Analytical thin layer chromatography was carried out on Merck silica $60 F_{254}$. Column chromatography was carried out with silica gel $60_{\mathrm{N}}$ (Kanto Chemical Co.). LRMS and HRMS were reported on the basis of TOF (time of flight)-MS (MADI-TOF or LCMS-IT-TOF), and DART (Direct Analysis in Real Time)-MS. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded with a 5 mm QNP probe at 400 MHz and 100 MHz , respectively. Chemical shifts are reported in $\mathrm{d}(\mathrm{ppm})$ with reference to residual solvent signals [ ${ }^{1} \mathrm{H}$ NMR: $\mathrm{CHCl}_{3}(7.26), \mathrm{C}_{7} \mathrm{H}_{8}(2.08), \mathrm{C}_{6} \mathrm{H}_{6}(7.16)$, $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5.32) ;{ }^{13} \mathrm{C}$ NMR: $\mathrm{CDCl}_{3}(77.0)$ ]. Signal patterns are indicated as s , singlet; d, doublet; t , triplet; q, quartet; m, multiplet; br, broad.
Synthesis of di-ol platform rac-1: (see Scheme 2) rac-1: Under an argon atmosphere, a solution of the cis-diquinoxaline spanned resorcin[4]arene ( $1.22 \mathrm{~g}, 0.9 \mathrm{mmol}$ ) in toluene ( 4 mL ) and DMSO ( 16 mL ) was stirred $55^{\circ} \mathrm{C}$ for 10 min , and followed by addition of $\mathrm{K}_{2} \mathrm{CO}_{3}(187 \mathrm{mg}, 1.35 \mathrm{mmol})$ and $\mathrm{CH}_{2} \mathrm{BrCl}(0.12 \mathrm{~mL}, 1.8 \mathrm{mmol})$. After 4 h the mixture was cooled to room temperature and filtered through a pad of Celite with eluent of toluene, and the filtrate was evaporated off. The residue dissolved into toluene was transferred into a separatory funnel, and washed with water ( 10 mL ) and brine ( $10 \mathrm{~mL} \times 3$ ), dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and concentrated in vacuo to give a crude of 1.20 g as a brown solid material. Synthesis of rac-19/rac-20: (Scheme 4) Under an argon atmosphere, to the one-neck flask charged with rac-16 (100 mg, $0.074 \mathrm{mmol})$ was added anhydrous toluene ( 2 mL ), $\mathrm{Et}_{3} \mathrm{~N}(0.025 \mathrm{~mL}$, $0.18 \mathrm{mmol})$, and allyl(dichloro)methylsilane ( $0.012 \mathrm{~mL}, 0.081 \mathrm{mmol}$ ). After stirred at ambient temperature for 2 h , the mixture was filtered through a pad of cotton and concentrated in vacuo to give a crude of 107 mg as a white solid material. Purification by silica-gel column chromatography (hexane/EtOAc $=9: 1$ ) afforded rac-19 of 28 mg as white solid materials ( $26 \%$ ), and rac-20 of 13 mg as white solid materials ( $12 \%$ ). Representative experimental sections for oxidation reactions of allylsilanes: (see Table 4) Under an argon atmosphere, to the oneneck flask charged with appropriate allylsilanes (rac-n, 0.019 mmol ) and anhydrous toluene ( 1 mL ) was added mCPBA ( 6.4 mg , 0.028 mmol ). After the reaction mixture was stirred for overnight, saturated aqueous $\mathrm{NaHCO}_{3}(3 \mathrm{~mL})$ was added at $0{ }^{\circ} \mathrm{C}$, and then toluene ( 10 mL ) and water ( 10 mL ) were also added. The aqueous phases were extracted with toluene, and the combined organic phases were washed with brine, and concentrated in vacuo to give crude products. Purification by short-plugged silica-gel column chromatography (hexane/EtOAc = 4:1) afforded diastereomeric mixtures of corresponding epoxides. ${ }^{1} \mathrm{H}$ NMR stacks (Figure S2, and S3) of diastereomeric mixtures of epoxides are given in Supporting Information.

[11] In each synthesis of rac-1, -12, -13, -14, and -15, two pieces of methylenes, pyrazines, and quinoxalines reacted with the tetra-ol platform to cause side-production of the corresponding symmetrical compounds which are summarized in Supporting Information. These over-reactions in ca. $20 \%$ yields decreased each productivity of the desired di-ol molecules.
